

Proxy discrepancies concentrate before evidence is complete

Native decisions use the logit-margin rule $\Delta > 0$; no $S > 0.5$ threshold is used

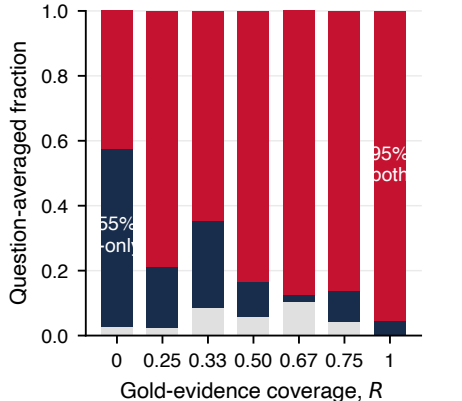

A J is positive across both native signs

B Agreement recovers with coverage

C Early mismatch is J -only sufficiency

Replica reliability: $r_J=0.98$, binary agreement=0.98; $r_\Delta=1.00$, sign agreement=0.99. B-C first average repeated states within each question-coverage pair.
